Vibration-based condition monitoring (VCM) is a well-known and well-accepted method for the health monitoring of rotating machines in industries. However the conventional VCM possesses some limitations in terms of using a number of vibration sensors at each bearing pedestal and sufficient experience to interpret the measured vibration data to identify fault(s), if any, present in the machine.

Ultrasonic analysis helps detect changes in sound patterns caused by problems such as leaks, wear, fatigue or deterioration. Ultrasound (i.e., high-frequency sound waves that are above human perception from 20 kHz to 100 kHz) is detected by an ultrasonic translator and converted to audible or visual output.
